My Physics of Time and Infinity

An Interpretive Research Essay on Time, Entropy, Relativity, Quantum Theory, Infinity, Everettian Unified Duality, and Consciousness-First Ontology

Thesis

I argue for **Everettian unified duality** with a **consciousness-first ontology**, and I separate what physics supports from what I personally commit to. The physics spine is time, entropy, relativity, quantum theory, cosmology, information bounds, and the limits of infinities. The metaphysical claim is that finite systems are locally real but not absolutely separate from the totality that contains them.

By **consciousness-first**, I mean that first-person interiority is ontologically fundamental rather than derived from non-experiential matter, while physical structure describes the public, lawful organization through which that interiority appears. This is not a new physical force, not a collapse theory, and not a claim that quantum mechanics proves consciousness.

I was shaped by many scientists and writers, but **Sean Carroll** has been the constant learning source for me for most of my life. His work on time, entropy, relativity, quantum foundations, and Hilbert-space realism gave me the language to discipline questions I already had about existence.

By **unified duality**, I mean two claims at once. First, **finite configurations** are genuinely distinct: bodies, memories, observers, and branches have local records, causal histories, and boundaries. Second, none of those configurations is finally outside the total structure that contains it. The phrase is a label for local distinction plus global belonging, not a new equation and not a proof of one universal subject.

Claim Status

Claim	Status	Support	Limit
Time is layered	Established physics plus open quantum-gravity work	Proper time, thermodynamic records, quantum time as a parameter, relational-clock models, and semiclassical time recovery.	No final theory of quantum gravity is established.
Finite local configurations	Physics-facing claim	Decoherence, density matrices, effective field theory, and entropy bounds describe bounded local systems inside wider structures.	This does not prove the final ontology of the whole.
Locality may be emergent	Serious unresolved research	Quantum-information approaches use entanglement and mutual information to reconstruct geometry in controlled settings.	No complete derivation of our universe from Hilbert space is established.
Everettian branches are real	Interpretive physics stance	Unitary quantum mechanics plus decoherence explains stable branch-like histories without adding physical collapse.	Everettian ontology and probability remain interpretive issues.
First-person interiority as fundamental	Metaphysical commitment	Physics correlates experience with physical structure but does not currently derive first-person presence from non-experiential matter.	No accepted experiment proves this ontology.
Ultimate totality	Personal metaphysical commitment	Everettian branching, eternal-inflation models, landscape reasoning, and quantum-cosmology proposals motivate very large structures.	No observer can step outside reality and measure the whole as an external object.

What This Essay Does Not Claim

This essay does not provide a completed theory of consciousness, does not prove that the universe is conscious, does not claim that quantum mechanics proves consciousness, does not claim that atoms think like humans, and does not turn every mathematical infinity into a literal physical infinity.

The careful statement is that physics supports **structural connectedness** more directly than total experiential unity. It gives equations, invariants, correlations, entropy gradients, density matrices, records, and information bounds. The stronger interior claim belongs to the metaphysical sections, where I mark it as commitment rather than physical proof.

Testability and Boundary

For physics, I do not want to pretend that an idea has been proven when it cannot be **tested, constrained, or connected to observation**. A hypothesis should not be treated as established physics just because it is beautiful, emotionally powerful, or mathematically attractive.

But not every real question fits cleanly inside the current experimental frame. First-person experience, meaning, death, and the presence of existence itself are not fake questions just because they are difficult to formalize. My standard is simple: keep scientific claims tied to testable structure, and keep metaphysical claims marked as metaphysical.

I also avoid treating the totality as a literal computer unless a specific mathematical model is being named. Computation is useful language for information, simulation, quantum circuits, and physical limits, but it becomes too loose if it replaces an argument. The bridge problem later in the essay is where that limitation matters most.

Physics and Math Spine

The quantum starting point is a state in Hilbert space evolving under a Hamiltonian. For a closed system with time-independent Hamiltonian, the clean unitary form is

$$U(t) = e^{-iHt/\hbar}.$$

This equation supports the claim that quantum evolution can be described without physical collapse if the system is treated as closed. It does not prove Everett by itself, and it does not prove any ontology of first-person interiority. Those are interpretive and metaphysical steps added after the formalism.

The finite-information side starts from black-hole thermodynamics. The central result is that black-hole entropy scales with horizon area:

$$S_{BH} = \frac{k_B c^3 A}{4G\hbar}.$$

Here S_{BH} is the entropy of the black hole, A is the horizon area, G is Newton's gravitational constant, c is the speed of light, $\hbar$ is the reduced Planck constant, and k_B is Boltzmann's constant. The important point is that entropy scales with area, not volume.

If a finite region has a maximum entropy, the number of independent states available to that region is also bounded in the entropy-counting sense:

$$\dim \mathcal{H}_R \lesssim e^{S_{\max}/k_B}.$$

This backs a disciplined version of finite configurations: finite regions may have finite information capacity. It does not prove that the totality itself is finite, infinite, conscious, or self-learning. It gives a serious physics reason to distrust the idea that continuum infinities in quantum field theory are final literal ontology.

The strongest mathematical bridge between separateness and structure is quantum information. Correlation between subsystems can be measured by quantum mutual information:

$$I(A : B) = S(A) + S(B) - S(AB).$$

Here $S(A)$, $S(B)$, and $S(AB)$ are von Neumann entropies of subsystem A , subsystem B , and their joint system. This supports the research idea that geometry and locality may be reconstructed from information relations. It does not prove that all distance is literally mutual information in our universe.

Decoherence gives the branch-and-record side of the essay a physical mechanism. A local system is described by tracing over environmental degrees of freedom:

$$\rho_S = \text{Tr}_E(\rho_{SE}).$$

This supports classical-looking records and stable histories. It does not prove that branches are ontologically real; that is the Everettian step. It also does not explain consciousness. It explains how local classical structure can appear inside quantum mechanics without adding a literal classical world by hand.

Types of Time in Physics

Type	Where It Appears	Status	Meaning
Coordinate time	Special Relativity and General Relativity charts	Conventional	A label used in a coordinate system.
Proper time	Special Relativity and General Relativity worldlines	Invariant and local	What an ideal clock measures along a path.
Cosmic time	Friedmann-Lemaitre-Robertson-Walker cosmology	Symmetry dependent	Proper time of comoving observers.
Thermodynamic time	Statistical mechanics	Emergent	Direction associated with entropy and records.
Quantum time	Standard quantum mechanics	External parameter	Parameter in Schrodinger evolution.
Relational time	Page-Wootters and quantum gravity	Research and interpretation	Time from correlations.
Semiclassical time	Wheeler-DeWitt and WKB limits	Approximate and emergent	Time recovered from an almost classical geometry.
Experienced time	Conscious observers	Philosophical and neurophysical	Lived sequence, memory, rhythm, and expectation.

Proper Time and Relativity

The first distinction is between coordinate time and proper time. The invariant spacetime interval is

$$ds^2 = g_{\mu\nu} dx^\mu dx^\nu.$$

For a timelike worldline and signature $(-+++)$,

$$d\tau = \frac{1}{c} \sqrt{-ds^2}.$$

Proper time is not the t -coordinate. It is the geometric quantity accumulated by an ideal clock carried along a path. In flat spacetime,

$$d\tau = dt \sqrt{1 - \frac{v^2}{c^2}}.$$

That is the core reason time dilation exists: the clock reading depends on the path through spacetime, not just on the endpoints in one coordinate frame.

A free relativistic particle follows a path that extremizes proper time. With standard conventions,

$$S = -mc \int ds = -mc^2 \int d\tau.$$

The Euler-Lagrange equations give the geodesic equation,

$$\frac{d^2 x^\mu}{d\lambda^2} + \Gamma_{\alpha\beta}^\mu \frac{dx^\alpha}{d\lambda} \frac{dx^\beta}{d\lambda} = 0.$$

So in relativity, time evolution for a free body is not motion through a fixed background time. It is worldline geometry determined by the metric connection.

The Arrow of Time

The deepest puzzle is not that equations contain a time variable. The deeper puzzle is why we remember the past and not the future, why broken cups do not unbreak, and why records accumulate in one temporal direction.

In statistical mechanics, entropy is tied to the volume of phase space compatible with a macrostate:

$$S_B = k_B \log W.$$

For a low entropy macrostate, overwhelmingly many compatible microstates evolve toward larger macroregions because those occupy vastly more volume. But this is not enough by itself. If microscopic laws are largely reversible, why do we almost always see entropy increase toward what we call the future rather than toward the past? A standard explanatory strategy is to combine statistical mechanics with a special low entropy boundary condition for the early universe, often called the **Past Hypothesis**.

For cosmology, the puzzle sharpens because the early universe was hot, smooth, and nearly homogeneous. Matter and radiation may have been close to local thermal equilibrium, but gravitational entropy was extremely low because gravity favors clumping, black hole formation, and large Weyl curvature. A smooth early FLRW universe is therefore thermodynamically special even if the plasma was hot.

Decoherence explains a different part of the story. If a system S interacts with an environment E , the reduced state is

$$\rho_S = \text{Tr}_E(\rho_{SE}).$$

Environmental entanglement suppresses interference terms in preferred pointer bases, stabilizing records and giving effective classical branches. But decoherence alone is not a complete arrow of time theory, because the formation of records still depends on a low entropy boundary condition.

Most microscopic laws used in mechanics, field theory, and unitary quantum mechanics are nearly time reversal symmetric in their core form. Strictly, the Standard Model is not perfectly time reversal symmetric: CP violation in the weak interaction implies T violation if CPT symmetry holds. That microscopic violation is not what explains the thermodynamic arrow, which is normally treated through statistical mechanics, records, and special boundary conditions.

Relativity and Cosmology

The geometric core of general relativity is the metric $g_{\mu\nu}$, and the dynamical core is the Einstein field equation:

$$G_{\mu\nu} + \Lambda g_{\mu\nu} = \frac{8\pi G}{c^4} T_{\mu\nu}.$$

In matter, geometry and stress energy lock together. This is the precise mathematical form behind the idea that matter tells spacetime how to curve, and curvature tells matter how to move.

Free massive particles obey the geodesic equation, while light follows null geodesics with

$$ds^2 = 0.$$

This makes proper time local and path dependent, while coordinate time remains a matter of foliation choice. In generic curved spacetimes, there is no preferred global time function with universal physical status.

In the ADM $3+1$ formalism, spacetime is foliated into spatial slices:

$$ds^2 = -N^2 c^2 dt^2 + h_{ij}(dx^i + N^i dt)(dx^j + N^j dt),$$

where h_{ij} is the spatial metric, N is the lapse, and N^i is the shift. The crucial conceptual point is that t here is a foliation label, while lapse and shift encode gauge freedom in how slices are stacked.

Cosmology gives back a cleaner time only after imposing symmetry. In FLRW spacetime,

$$ds^2 = -c^2 dt^2 + a(t)^2 \left(\frac{dr^2}{1 - kr^2} + r^2 d\Omega^2 \right).$$

Here t is cosmic time, the proper time of comoving observers. For a comoving observer, $dr = d\theta = d\phi = 0$, so $ds^2 = -c^2 dt^2 = -c^2 d\tau^2$ and $d\tau = dt$. Cosmic time is therefore not Newton's absolute time; it is the proper time of a special family of observers selected by large-scale homogeneity and isotropy.

The Friedmann equation is

$$H^2 = \left(\frac{\dot{a}}{a} \right)^2 = \frac{8\pi G}{3} \rho - \frac{kc^2}{a^2} + \frac{\Lambda c^2}{3}.$$

It relates expansion, density, curvature, and the cosmological constant.

Horizons and Inflation

Horizons sharpen the distinction between local time, global time, and observable time. In FLRW models, the particle horizon and event horizon are

$$d_p(t) = a(t) \int_0^t \frac{c dt'}{a(t')},$$

$$d_e(t) = a(t) \int_t^\infty \frac{c dt'}{a(t')}.$$

The particle horizon is about what can have influenced us by time t . The event horizon is about what we can ever influence or observe in the future. The Hubble radius c/H is important, but it is not generally identical to either horizon.

Inflation is the standard early universe mechanism for explaining near flatness and large-scale causal uniformity. The acceleration condition is

$$\ddot{a} > 0.$$

For a scalar inflaton field in natural units,

$$\rho_\phi = \frac{1}{2}\dot{\phi}^2 + V(\phi),$$

$$p_\phi = \frac{1}{2}\dot{\phi}^2 - V(\phi).$$

Potential domination gives accelerated expansion. Inflation remains one of the strongest theoretical bridges between early universe physics and observations, but the inflaton identity, the measure problem in eternal inflation, and the status of global infinities remain unresolved.

Quantum Time

In ordinary nonrelativistic quantum mechanics, time enters as an external parameter:

$$i\hbar \frac{\partial}{\partial t} |\psi(t)\rangle = \hat{H} |\psi(t)\rangle.$$

The basic architecture is a one-parameter unitary group generated by the Hamiltonian. Position, momentum, and spin are operators. Time is usually the parameter with respect to which they evolve.

The Pauli style objection matters here only because it reinforces the layered view of time. If a self-adjoint operator $\hat{T}$ were globally canonical conjugate to a semibounded Hamiltonian $\hat{H}$, then the unitary transformations generated by $\hat{T}$ would shift the spectrum of $\hat{H}$ through arbitrary real values, contradicting the lower bound:

$$[\hat{T}, \hat{H}] = i\hbar.$$

That blocks a universal canonical time operator under those assumptions. It does not block operational time observables, arrival-time POVMs, or special restricted constructions. Time can be a parameter in ordinary quantum mechanics, a clock reading in relativity, a correlation in relational constructions, and a lived sequence in conscious memory without being the same object in every context.

The path integral formulation reframes evolution as a sum over histories:

$$K(b, a) = \int \mathcal{D}x e^{iS[x]/\hbar}.$$

This does not remove time from ordinary quantum mechanics. It rewrites time evolution in terms of amplitudes assigned to paths.

A more radical move is relational time. In Page-Wootters style constructions, a total stationary state may satisfy

$$\hat{H}_{\text{tot}} |\Psi\rangle = 0,$$

while conditional subsystem states recover effective time evolution through correlations with a clock subsystem. Time becomes correlation, not background. This is elegant, but idealized. It depends on a good clock sector, appropriate factorization, and coherence.

Wheeler-DeWitt and Semiclassical Time

In canonical quantum gravity, the Hamiltonian constraint becomes an operator equation. The Wheeler-DeWitt equation is best treated here as schematic because the actual canonical theory contains local Hamiltonian constraints, momentum constraints, factor-ordering choices, regularization issues, and an unresolved physical inner product. In schematic form it is often written as

$$\hat{H}\Psi = 0.$$

There is no external t here. The universal state is described by a constraint, not by a time-dependent Schrodinger equation.

To recover ordinary time, one can use an approximate semiclassical form such as

$$\Psi[h_{ij}, \phi] \approx e^{iS_0[h]/\hbar} \chi[h_{ij}, \phi].$$

At leading order, S_0 defines a classical spacetime background. At the next order, χ obeys an approximate Schrodinger equation for matter on that background:

$$i\hbar \frac{\partial \chi}{\partial t_{\text{WKB}}} = \hat{H}_m \chi.$$

Here t_{WKB} is an emergent semiclassical time read off from the gravitational background, not a fundamental external variable.

Infinity in Physics

Infinity is not one thing. Mathematical infinity, ultraviolet divergence, vacuum energy divergence, singularity, and cosmic or global infinity have different meanings.

Fields assign values to spacetime points. Hilbert spaces may be infinite dimensional. Configuration spaces can be continuous. These infinities often belong to the representational language of the theory, not directly to observables.

Ultraviolet divergences appear in perturbative quantum field theory loop integrals. A representative regulated integral has the form

$$I(\epsilon) = \frac{A}{\epsilon} + B + O(\epsilon).$$

The pole in ϵ is not interpreted as a literal measurable infinity. It is absorbed into bare parameters, after which renormalized predictions are finite and scale dependent. The renormalization group tracks this scale dependence:

$$\mu \frac{dg}{d\mu} = \beta(g).$$

Vacuum energy creates a deeper problem because gravity couples to absolute stress energy. In free field language, vacuum energy includes a formally divergent zero-point contribution:

$$\rho_{\text{vac}} \sim \frac{1}{2} \int \frac{d^3 k}{(2\pi)^3} \hbar \omega_k.$$

In nongravitational quantum field theory, only energy differences are usually observable. With gravity, the absolute scale matters. That is why the cosmological constant problem remains severe.

Singularities are different again. In general relativity, the cleaner criterion is often geodesic incompleteness, not simply a point of infinite density. A singularity theorem tells us where the classical spacetime description ceases to be extendable, not what a complete quantum gravitational theory would say.

The Schwarzschild horizon is the radius

$$r_s = \frac{2GM}{c^2}.$$

That surface is not a curvature blowup. By contrast, the central singularity is different because the Kretschmann scalar diverges there:

$$K = \frac{48G^2 M^2}{c^4 r^6}.$$

The horizon is mostly a coordinate artifact. The center is an incompleteness signal for classical general relativity.

Cosmic Infinity and Many Origins

Cosmic infinity is subtler than it sounds. Even if spatial slices are globally unbounded, our observable domain is finite because the universe has finite age and finite causal horizons.

Exact de Sitter spacetime has a horizon scale

$$R_{\text{dS}} = \sqrt{\frac{3}{\Lambda}}.$$

More generally, horizon integrals determine what is in principle observable, not the bare global topology. Infinite universe, infinite observable universe, and every possible configuration are not the same claim.

Eternal inflation pushes infinity to its cosmological extreme. Inflating regions may continue producing new thermalized regions, potentially without bound. This creates a route to multiverse pictures and infinite ensembles of pocket universes. But it also creates the measure problem: probabilities become ambiguous when comparing infinite numbers of events, regions, or observers.

I treat eternal inflation, quantum tunneling cosmologies, landscape reasoning, and Everettian branching as serious pressure points, not as established proof of my metaphysical view. They weaken the idea that reality must have one privileged beginning, one privileged vacuum, or one privileged outcome.

Everettian Framework and Unified Duality

The Everettian interpretation is the physics-facing framework I find most coherent because it takes unitary quantum evolution seriously and does not add a separate physical collapse process. On that view, what we call different outcomes are stable branches of one quantum structure.

The universal wave function gives a disciplined meaning to one part of my unity claim: branches are not disconnected realities floating apart from one another; they are distinct local structures inside one total state. That is a structural claim. It does not yet prove an experiential claim.

This is not the same as saying every logical fantasy exists. The disciplined version is narrower: every branch or configuration physically supported by the real universal state belongs to reality. From inside one branch, a finite observer experiences one outcome. From the total-state view, the quantum structure contains all outcomes that the state actually supports.

In this framework, **unified duality** means local distinction plus global belonging. Each branch contains its own records, observers, histories, and causal structure; none of those branches exists outside the universal state. The rigorous part ends there. The stronger claim about final experiential unity belongs to my metaphysical commitment, not to established quantum mechanics.

Finite Hilbert Space and Emergent Locality

A physics-facing framework that sharpens this view starts from a Hilbert space, a quantum state, and a Hamiltonian. In that framing, quantization is not something nature does to itself; it is a human procedure for translating classical variables into quantum language. Nature would simply be quantum from the start, while classical physics would be the large-scale approximation that finite observers learn first.

Black-hole entropy and holographic reasoning suggest that a finite region of space may have a finite information capacity. If that is correct, then the infinite-dimensional continuum used in quantum field theory is not the final ontology of nature. It is an extraordinarily successful approximation, useful inside its domain, but not necessarily the deepest description of a finite physical region.

In that kind of picture, locality is not assumed at the start. The basic ingredients are the state, the Hamiltonian, and the operator structure. The operators that appear local to us would have to emerge from how the system factors into stable subsystems. Regions with strong shared information or entanglement behave as close. Regions with weak shared information behave as far. Space becomes a pattern of relation, not an empty container that was simply given in advance.

Gravity can then be read as geometry responding to quantum information. In research programs that connect entanglement, modular Hamiltonians, and spacetime geometry, Einstein-like gravitational behavior is not inserted as the first fact; it is recovered from deeper quantum structure under special limits. I treat that as a serious research direction, not as a completed theory.

Branching also needs discipline. Not every mathematical factorization of a Hilbert space is a world. A branch needs decoherence, records, an entropy gradient, and stable observer-like systems that can carry a history. A globally stationary state by itself is not a lived sequence of events. For anything to appear as a world, information has to become redundantly stored in an environment, creating the stability that lets a finite perspective say: this happened.

This gives mechanical discipline to my phrase **finite configurations inside one totality**. The physics-facing side says that local systems may be emergent patterns inside a deeper quantum structure. Whether finite perspectives also carry intrinsic interiority is the bridge problem, not a result derived from entanglement or holography.

Generative Variation and Many Origins

One pattern I see everywhere is variation: many species, many bodies, many stars, many minds, many possible lives, and many branch-relative histories. Reality does not appear as one form repeated without difference. It appears through families, alternatives, mutations, branches, and scales.

Physics gives disciplined ways to think about plurality without pretending the whole is already mapped. Everettian quantum mechanics gives branch structure. Eternal-inflation models discuss bubble regions. Landscape reasoning discusses many possible vacuum states. Quantum-cosmology proposals discuss different boundary conditions and origin routes. These are not all proven as literal descriptions of reality, but they make a single privileged outcome look less compulsory.

When I say **ultimate totality**, I mean the complete reality that would contain every physically real branch, region, field, law, boundary condition, observer, and history. It should not be imagined as one object sitting inside a larger outside space. It is the whole frame, so there is no external laboratory from which it can be measured as a separate object.

A totality without an absolute beginning or final boundary would not have to be static or uniform. It could contain regions with different ages, horizon sizes, effective laws, vacuum states, histories, and physical organizations. That is the normal version of my claim: not that I can prove every possible world exists, but that the deepest reality may be larger than any one observable region, one branch, one vacuum, or one cosmic history.

Repetition and variation are therefore not opposites. In a sufficiently large reality, exact repetitions, near repetitions, and radically different structures may all be possible depending on the measure, dynamics, and state space. I cannot test that full claim from inside one observable region, so I keep it as metaphysical interpretation rather than established cosmology.

First-Person Interiority and the Bridge Problem

The physics in this essay can support structural unity, finite information capacity, emergent locality as a serious research program, decoherence, records, and the possibility that time is not fundamental in every formulation. It cannot currently turn the totality into a laboratory object, compare our universe with all possible universes, or derive first-person presence from equations alone.

The hard question for my view is the **bridge problem**: how does primitive interiority become organized into finite self-systems with memory, attention, embodiment, language, values, and a stable sense of being one person? Naming interiority as fundamental does not solve that. It only rejects the idea that experience appears from a reality with no intrinsic experiential aspect anywhere.

A serious bridge theory would need constraints. It would have to respect known physics, ordinary neuroscience, decoherence, thermodynamics, and the fact that human minds depend on physical records and causal organization. If it changed quantum statistics, measurement theory, or branch weights, it would need a testable law. Without that, it is an ontology of interiority, not a new physical mechanism.

The bridge also has to be branch-local. In an Everettian universe, there is not one ordinary human ego floating above all outcomes and choosing which branches become real. There are finite self-systems inside decohered histories, each with its own records and future. A bridge theory would need to explain how a local perspective arises inside a branch without erasing the reality of counterpart perspectives in other branches.

The shape of a solution would probably involve lawful relations between physical record structures, self-modeling, attention, memory, embodiment, and intrinsic interiority. I do not have that law. That is why I treat the commitment as metaphysics constrained by physics, not as completed science.

Objections I Take Seriously

The first objection is against **Everettian realism**. If all outcomes happen, probability becomes difficult: why expect one outcome rather than another if every branch exists? My answer is not that the problem disappears. It is that probability becomes branch weight, self-location, and rational expectation inside a branching structure. That is a technical problem, not a slogan.

The second objection is about ontology. A critic can ask whether branches are truly worlds or only useful descriptions after decoherence. I take that seriously. My answer is that if the universal wave function is real and no physical collapse removes the other terms, treating the other decohered branches as unreal feels less coherent than accepting them as real parts of the total state.

The third objection is against **unified duality**. Physics connects systems through shared laws, common origin, fields, geometry, and quantum structure, but it does not automatically prove that local self-systems ever become the totality itself. I accept that. The rigorous claim is only that local systems are real as bounded records and histories while none of them exists outside the total physical structure.

The fourth objection is about the interiority commitment. Someone can say that atoms, molecules, and inanimate matter behave the way they do because of physical law, not because consciousness is present in them. I accept the public description. My claim is not a new force and not a replacement for physics. It is a claim about the intrinsic nature of lawful reality, and the bridge theory remains unfinished.

The fifth objection is **free will**. A unitary Everettian universe does not give me libertarian freedom in the sense of an uncaused chooser standing outside physics. If I use the phrase free will, I mean branch-level agency: deliberation, attention, memory, values, inhibition, and self-control are real causal processes inside a finite self-system.

Branch-level agency means the agent does not choose which branches exist globally. The agent is the branch-local process by which reasons, memories, emotions, and values become correlated with later records and actions. Nearby counterpart agents may make different choices in other branches, but that does not make deliberation fake inside this branch. It rejects outside-the-wavefunction choice while preserving agency as a real pattern of reasoning and self-control inside a causal history.

My Own Criterion for Infinity

The original synthesis I defend is a practical criterion for separating an infinity that is mostly an artifact from an infinity that signals incompleteness. An infinity is an **artifact** when changing the regulator, cutoff, coordinates, or idealization leaves the finite observable predictions stable inside the theory's intended domain. It is an **incompleteness signal** when removing or changing the infinity forces new empirical input, breaks invariant evolution, or makes predictions depend on unknown physics outside the theory's domain.

More formally: an infinity is an artifact when it can be removed or absorbed into scale-dependent parameters without changing observable dimensionless ratios $R_i(\mu)$ at the scale μ where the theory is being tested. It is an incompleteness signal when predictions at μ cannot be made stable without new physics, new boundary data, or a replacement of the theory's invariant structure.

That is why many ultraviolet divergences in renormalizable quantum field theory behave like artifacts of description, while gravitational singularities and the cosmological constant problem feel deeper. The first can often be absorbed into scale-dependent parameters without losing predictive control. The second and third point toward missing structure: either a breakdown of classical spacetime, or a mismatch between quantum vacuum reasoning and dynamical gravity.

I use a parallel criterion for experienced time. If every report, memory, anticipation, and ordering judgment supervenes on records embedded in geometry, entropy gradients, and intrinsic interiority, then experienced time is explained by records plus physical organization plus intrinsic interiority. If two physically identical

record structures could differ in lived temporal flow with observable consequences, then that explanation would fail. I do not know the answer, but that is the kind of distinction that would make the question sharper.

Personal Vision Appendix

This appendix is not part of the claim-status table. It is where I place the belief that the ultimate totality does not merely contain finite perspectives but comes to know limitation, contrast, memory, pain, beauty, and variation through them. I use the word **learn** here personally, not as a measurable biological or computational process applied to the whole of reality.

The scientifically disciplined version is weaker: finite observers produce records, compare states, store memories, and occupy branch-relative histories. My personal vision adds that these finite perspectives are not meaningless fragments. They are how a deeper reality becomes concrete from within without being exhausted by any one life, world, or branch.

Open Questions

- Why was the early universe in such a low entropy condition?
- Was the early universe special because of low gravitational entropy, low Weyl curvature, or a deeper boundary principle?
- Is the Past Hypothesis a law, a boundary condition, or an explanatory postulate?
- How should gravitational entropy be defined generally?
- Is time fundamental or emergent?
- What is the correct quantum gravity framework?
- Can relational time survive realistic imperfect clocks?
- Are Everettian branches fully real worlds or emergent structures inside one universal state?
- Is variation only a biological and cosmological pattern, or a deeper generative feature of existence itself?
- Which infinities are artifacts, and which infinities signal incompleteness?
- Are global infinities physically meaningful or observationally inaccessible?
- Can finite self-systems ever experience the totality without erasing local difference?
- Can physics explain consciousness itself, or will it need a theory of intrinsic experience in addition to the structures correlated with it?
- Can consciousness, meaning, death, and first-person presence ever be exhausted by mathematics, physics, computation, or laboratory testing?

Final Synthesis

My conclusion is not that physics proves unity, timelessness, or cosmic consciousness. It is that physics weakens simple absolutes: time can be local, thermodynamic, relational, and semiclassical; infinity can be a tool, a warning, or a speculative horizon; and local systems can be real without being absolutely separate.

My final position adds Everettian realism, **unified duality**, a consciousness-first ontology, and generative variation. Those additions are not established physics. They are the disciplined metaphysical form my intuition takes after passing through equations, records, entropy, geometry, and quantum structure.
